

SECTION II

CODE INFORMATION

General

This section contains code information for all AF, AG, AJ, AK, AL, and AM relays that have been coded on the date of issue. The information is arranged in a form to facilitate the selection of relays to meet particular circuit requirements.

The relay code information, ie, code number, spring combination, winding, and adjustment information, is listed in Tables II-1, II-2, II-3, and II-4 according to the number of contacts on each code. Each M, B, EM, EB, PM, and PB contact arrangement counts as one contact. Each EMB, BM, and EMB contact arrangement counts as two contacts.

To locate the design information for a particular coded relay, lists of codes in numerical order are provided preceding Table II-1. These show the table number and the number of contacts where this information may be found.

High-Operation Relays

Wire spring relays that are expected to operate several hundred million times in a 40-year life require the use of special long-life features to avoid the necessity of periodic readjustments to compensate for wear. These special features consist of heavy chromium plate on the armature, core, and core plate; No. 1 metal stop discs; and stainless steel wear pads on the core legs in the region where the armature pivots. The number of operations, in millions, for which relays with different coils are satisfactory without the use of the long-life features are:

Res	1 to 6 Contacts		Over 6 Contacts	
	S	Travel	I	Travel
16	150	100	200	150
270	250	200	300	250
400	300	200	300	300
700	350	300	400	350
Over 700	400	350	400	350

Relays that operate in excess of these figures should be equipped with the long-life features. Relays with the long-life features are coded in a separate code series. These relays should not be used unnecessarily since the long-life features increase the cost of the relay by approximately 15 cents.

Code Numbers

The following blocks of code numbers have been established for the AF, AG, AJ, and AK relays. There is only one code series each for the AL and AM relays.

<u>Ordinary Relays</u>	
<u>1 to 12</u>	<u>Contact Positions</u>
AF1 to 499	24 Makes
AJ1 to 199	None
AG1 to 199	AJ200 to 299
AK1 to 499	None
	None

<u>Long-Life Relays</u>	
<u>1 to 12</u>	<u>Contact Positions</u>
AF500 and up	24 Makes
AJ500 to 699	None
AG	AJ700 to 799
AK500 and up	None

At the present time, there are 459 codes of wire spring relays being manufactured. This number includes all the basic types listed above and represents many combinations of winding resistances and contact arrangements. Special requirements, such as long-life features, or nonstandard adjustments, will result in a slight increase in price of the relay.

It is economical to use relays having spare contacts on the following basis before considering a new code with the exact number of contacts required.

<u>Demand per 10,000 Lines</u>	<u>Permissible Spare Contacts</u>
800 - 400	1
400 - 200	2
200 - 100	3
100 - 80	5
80 - 60	6
60 - 50	8
Less than 50	10

Procedure

Count the total number of required contacts (M, B, EBM, etc). For AF and AJ relays, look in Table II-1 for single-wound or in Table II-2 for multiple-wound relays, starting with the total number of contacts required. For AG relays look in Table II-3, and for AK relays, Table II-4. AL relays are listed in Tables II-1A and II-2A and AM relays in Table II-4A. If the exact combination is not coded, then select the code available having the lowest number of contacts that will meet the requirements and determine if this design is economically satisfactory for the known demand.

If a satisfactory relay is not found in these tables, submit a wire spring relay request in duplicate to the relay requirements group (Form E-973A).

Adjustments

The Western Electric Company adjusts all U, UA, and Y relays furnished on wired equipments in the wiring shop, and uses the current flow values shown in the Circuit Requirements Table. With this program, the current flow values on the Circuit Requirements Table need not be the same as the M specification.

With the introduction of the wire spring relay, the Western Electric Company feels that it is more economical to adjust these relays in the relay assembly shop. This is due to the greater stability of the relay, the use of fewer adjustable features resulting from more preformed and pretensioned springs, the expectation of less adjusting effort, and the mass adjustment of the same code of relay. This program also permits the establishment of a single adjusting shop instead of one in the assembly shop and another in the wiring shop. The circuit requirements values must therefore be no more severe than the M specification values in order to avoid checking and readjusting effort in the wiring shop.

It will not be permissible to specify requirements on the Circuit Requirements Table that are not a part of the M specification. Where a relay requires current flow values different from those in the M specification, it will be necessary to change the M specification or to issue a new code with the new adjustment. The choice of which procedure is to be followed will be determined by the economics of the situation. If the M specification is changed, the more expensive adjustment must be applied in the shop to all relays of that code, which might be uneconomical if there existed a high demand for the relay without the additional requirements. On the other hand, a new code for a relay with a small use would result in an increased overall production cost by manufacturing more small-lot orders. The cost of the two methods must be compared to determine the most economical procedure. Section XI contains the data for making this comparison. On low-demand uses, a new code cannot be justified because the existing code has extra adjusting requirements.

Where a multiplicity of requirements is shown in Tables II-1, II-2, and II-4 for AF, AJ, and AK relays, all of them need not necessarily be shown on the Circuit Requirements Table for every circuit application. Those requirements that do not apply to a particular circuit condition may be omitted. For instance, a nonoperate requirement should not be shown if there is no non-operate condition in the circuit. Check adjustments on other windings are not considered as additional requirements, and therefore may be used on the circuits without affecting the M specification. For example,

*TEST & READJUST REQUIREMENTS
CURRENT REQUIREMENTS*

if a relay is adjusted with two windings series aiding, a check adjustment may be shown for either winding alone in a particular Circuit Requirements Table even though it is not specified in the M specification.

The current flow requirements for the coded relays in Tables II-1, II-2, and II-4 are ~~readjust requirements~~. The test requirements are 105 percent of the operate and hold requirements and 95 percent of the nonoperate and release requirements.

Both test and readjust current flow requirements are shown for AG relays in Table II-3. The margin between release test and readjust for these relays is on an ampere turn rather than a percentage basis to provide margin for wear. The margin between test and readjust is 5 percent for operate, nonoperate, and hold requirements.

For AG relays, always specify the soak, operate, hold and release requirements.

Show "FS" in the "After Soak" column of the Circuit Requirements Table when soak currents are given, provided the full soak obtained under the test condition is equal to, or greater than, the specified value. If the full soak exceeds 0.7 ampere, the specified soak should be used.

Armature Back Tension

Armature back tension other than the standard (minimum 30 grams for AF, AJ, and AK relays; minimum 45 grams for relays with 24 makes or 24 breaks; minimum 20 grams for AG relays) must be shown in the Circuit Requirements Table.

Contact Gauging

Contact gauging values other than standard are shown in Tables II-1, II-2, II-3, and II-4 and must be shown in the Circuit Requirements Table.

A visual check, without gauges, will be made for all EBM, EMB, PBEM, and PMEB spring units. No check is made for any other sequence unless the sequence is specified in the Circuit Requirements Table.

Resistance Tolerances

Unless otherwise stated, the resistance variation of inductive windings is ± 10 percent and noninductive windings is ± 5 percent. All resistance values are based on 68° F.

Contacts

Only palladium (No. 2 metal) contacts of one size are used on AF, AG, AJ, AK, AL, and AM relays. The twin-wire contacts have a thin gold overlay.

Battery Connection to Springs

Battery and ground shall not be connected to springs in adjacent positions, since these springs may be shorted by the contact burnisher.

Contact Force

The AF, AG, AJ, AK, AL, and AM relays are generally designed to provide a nominal 12.5-gram contact force. The sensitive relays are designed to provide a nominal 8-gram force. A high contact force range is available that provides a minimum 15-gram force. Since the contact force is non-adjustable, no reference is made to it in the Circuit Requirements Table.

Armature Travel

The armature travel is nonadjustable and so should not be specified in the Circuit Requirements Table. The nominal armature travels, measured at the card, are:

	Travel Inch	Contact Sequence	Spring Combination Number
Short	0.026	1 Stage	1 to 199, 500,501
Intermediate	0.044	2 Stage	200 to 399
Long	0.060	3 Stage	400 to 499

Operate and Release Times

The operate and release times for the AF, AG, AJ, and AK relays are shown in Table II-5, II-6, II-7, and II-8. These times are based on local circuit operation, 45 to 50 volts and no contact protection. The operate times are not shown for the relays that cannot be used in local circuit on 48 volts.

AL and AM relays are normally pulse operated and, hence, their operate and release times are circuit-dependent. For this reason, timing values are not generally listed; instead, they are specified as manufacturing requirements, where appropriate.

Circuit Preparation

Wire spring relays may be blocked in the operated or the unoperated position, and

their contacts may be insulated. When a make-contact on the relay under test is insulated, the margin between the readjust and test operate should be increased to 10 percent to compensate for the effect of the contact insulator on the operate current.

Winding terminals are extended to the front of the relay to provide connecting points for test purposes. The single-wire contacts may be used as connecting points for test purposes. This connection is made by a test prod that plugs into a 360 tool, as shown in Fig. VIII-1. The physical size of the 360 tools makes it impossible to pick up adjacent contacts without interference. At least two contact positions should be left between contacts to be picked up. As an exception, only one contact position need be left between connecting points straddling the center of the spring combination because of the wider space between contacts 6 and 7.

Maintenance Specifications

The following Bell System Practices cover the information for maintaining the wire spring relays.

A. Equipped with 0.014-inch stop discs.

C. Equipped with 0.147-inch copper sleeve.

W. Armature back tension minimum 20-gram readjust, 15-gram test.

(AM). Frame of relay grounded by mounting screws. Not recommended for general use.

(RA). Resistance ± 5 percent.

Notes:

- BD. Adjusted on heavy contact force.
 BG. Winding arrangement No. 11.
 BK. Armature back tension minimum 40-gram readjust; 35-gram test.
 BL. Armature back tension maximum 110-gram readjust; 115-gram test.
 BM. Soak current shall not flow for more than 5 seconds.
 BN. Operate and nonoperate test after soak and no flux release.
 BO. Release and nonrelease test after soak.
